S1 Series of Experimental Methods for Few-Layer MXene Synthesis: Identifying the Optimal Approach

In this study, a total of 16 experiments were conducted to identify the most suitable condition for preparing few-layer MXene. The experimental conditions, including etching type, stirring time, autoclave temperature, and time, were listed in Tables S1-S16 for each method. SEM analysis for each sample obtained through all the methods was conducted, and the results are presented in Figs. S1 and S2 only for the methods that yielded more distinct and observable interlayer spacing. Fig. S1 specifically highlights the methods that yielded larger interlayer spacing and achieved MXene with a stacked-layer thickness of less than 1 μm . The most promising results were achieved when the MAX phase was stirred in HF (48%) for 36 h and then transferred to a simple autoclave, heated at 150°C for an additional 36 h (Fig. S1f, Fig. S2, and Table S15). This indicates that stirring alone did not significantly etch the A-layer from the MAX phases, resulting in approximately 500 nm thick layer-stacks in the MXene flakes (Fig. S1a and Table S1-1-2). However, transferring the stirred sample to a normal autoclave led to a reduction in thickness to around 150 nm, indicating the importance of applied pressure for effective etchant penetration (Fig. S1f, Fig. S2, and Table S15). Based on these results, a high-pressure stainless-steel autoclave was used, applying both stirring and pressurizing processes simultaneously. This strategic approach further increased etchant penetration between layers and enhanced interaction with a larger number of flakes, thereby achieving uniform layer-stacked thicknesses of about 50 nm throughout all MXene flakes even prior to the exfoliation process (Fig. S1(g-i)), indicating significant removal of the remaining Al. Subsequently, the product underwent 7 hours of tip-sonication and was washed using centrifugation. The sediment collected from the bottom and upper part of the centrifuge tube revealed a stack-layer thickness of about 1~2 μm (Fig. S1j) and <100~600 nm (Fig. 1a and Fig. S3(a-f), respectively). This confirmed that the hybrid HF-Hydrothermal synthesis condition played a critical role in effectively controlling MXene thickness, providing a promising approach for producing few-layer MXene materials with enhanced properties.

Afterward, the sediment collected from the upper part of the centrifuge tube was dispersed in water and diluted to a 10-fold dilution compared to the as-collected sediment concentration (Fig. S4a). The diluted MXene sample was mixed with methanol and transferred dropwise into a beaker containing chloroform solvent, with a Si-wafer positioned at the bottom. Due to the immiscibility between methanol and chloroform created an interface where the few-layer MXene flakes (<100 nm) self-assembled, aligning their size with that of the substrate on the upper surface of the chloroform solvent (Fig. S4b). Subsequently, excess chloroform was removed, and the film level was adjusted to match the substrate. Finally, the substrate was lifted and subjected to a drying process at 100 °C for approximately 30 min to ensure the complete dryness of the MXene's film, revealing a thickness of <50 nm (Fig. 1b and Fig. S3a-c). The main steps involved in this process are illustrated in Schematic. 1 (a-f).

Table S1 Method-1: Different Stirring time

| S.No | Sample | solution | Stirrer time | Autoclave | Washing | Freeze-dry | Exfoliation in DMSO |
|------------|-------------------------------------|----------|--------------|-----------|----------|------------|---------------------|
| Method-1-1 | 1g, Ti ₃ AC ₂ | 20 ml HF | 24 h | — | pH ~ 6.0 | 48 h | 2h |
| Method-1-2 | 1g, Ti ₃ AC ₂ | 20 ml HF | 36 h | — | pH ~ 6.0 | 48 h | 2h |
| Method-1-3 | 1g, Ti ₃ AC ₂ | 20 ml HF | 48 h | — | pH ~ 6.0 | 48 h | 2h |

Table S2 Method-2: Different Stirring time

| | | | | | | | |
|------------|-------------------------------------|------------------------------|------|---|----------|------|----|
| Method-2-1 | 1g, Ti ₃ AC ₂ | 6 ml DI, 12ml HCl, & 2 ml HF | 24 h | — | pH ~ 6.0 | 48 h | 2h |
| Method-2-2 | 1g, Ti ₃ AC ₂ | 6 ml DI, 12ml HCl, & 2 ml HF | 36 h | — | pH ~ 6.0 | 48 h | 2h |
| Method-2-3 | 1g, Ti ₃ AC ₂ | 6 ml DI, 12ml HCl, & 2 ml HF | 48 h | — | pH ~ 6.0 | 48 h | 2h |

Table S3 Method-3: Different time and 60 °C in the thermal oven

| | | | | | | | |

S3 Synthesis of Cl-MXene via molten salt approach

The Cl-MXene was prepared using a CuCl_2 molten salt approach. This method did not involve high-pressure and stirring treatments, resulting in a smaller interlayer separation, as shown in Fig. S6a. The XRD pattern showed a slight shift in the (002) plane from 13.95° to 12.25° (Fig. S6b), confirming reduced interlayer spacing.

S7 Role of functionalization on the electrical and environmental properties of MXene

In this comprehensive study, we investigated the resistivity and conductivity of different MXene samples, including as-prepared MXene, Br-MXene, and I-MXene, as given below. Our findings revealed distinct conductivity values for each variant. For I-MXene, the conductivity was measured to be 449.9640029 S/m, while Br-MXene exhibited a conductivity of 394.29067 S/m, and as-prepared MXene showed a conductivity of 341.320226 S/m. Interestingly, recent studies have reported that de-functionalized MXene exhibits higher conductivity compared to functional group-based MXene. This observation can be attributed to the trapping of electrons by functional groups in the MXene channel (Ti₃C₂). Upon de-functionalization, these trapped electrons are released and reintegrated into the Ti₃C₂ structure, resulting in higher conductivity. Consequently, MXenes with high electronegative functional groups, such as -O, -OH, and -F, are expected to exhibit lower conductivity due to their higher tendency to trap electrons from the Ti₃C₂ MXene. Consistent with these findings, our study demonstrated that MXenes with -O, -OH, and -F-based functional groups exhibited lower conductivity compared to MXenes with lower electronegative terminal groups such as -I and Br-. This correlation highlights the influence of the terminal group's electronegativity on electron trapping and conductivity in MXene materials. These results not only contribute to a better understanding of MXene properties but also pave the way for tailoring MXenes with specific functional groups to achieve desired electrical characteristics for diverse applications in electronics, energy storage, and sensors.

Conductivity calculation

For I-MXene:

Resistance (R) = 3705 Ω

Length (L) = 0.5 cm = 0.005 m

Width (W) = 0.3 cm = 0.003 m

Thickness (T) = 0.6 μm = 0.0000006 m

Area (A) = W * T = 1.8E⁻⁹ m²

Resistivity (ρ) = R * (A / L) = 0.00133344 Ω .m

Conductivity (σ) = 1 / ρ = 749.9400048 S/m

Schematic S1 Conductivity measurement for MXene film over Si-wafer.

For Br-MXene

Resistance (R) = 4227 Ω

Resistivity (ρ) = R * (A / L) = 0.00152172 Ω .m

Conductivity (σ) = 1 / ρ = 657.1511185 S/m

For As-prepared-MXene

Resistance (R) = 4883 Ω

Resistivity (ρ) = R * (A / L) = 0.00175788 Ω .m

Conductivity (σ) = 1 / ρ = 568.8670444 S/m

Moreover, the stability of both I-MXene and as-prepared MXene was evaluated in ambient and aqueous environments. In the ambient environment, I-MXene exhibited reasonable stability for up to 80 days, with a 176% change in resistance. However, beyond the 150th day, a substantial increase in resistance exceeding 203,882% was observed, indicating significant instability. On the other hand, as-prepared MXene showed an extremely high change in resistance, reaching 99,613% by the 90th day, with no response observed beyond 110 days. In the aqueous environment, I-MXene exhibited an initial increase in resistance of about 172% during the first week, followed by more dramatic changes of 25,762% and 255,665% in the second and third weeks, respectively. Eventually, in the fourth week, no response was detected, suggesting complete oxidation. On the other hand, as-prepared MXene demonstrated significant increases in resistance, with a change in response reaching 16,903% in the first week and 186,385% in the second week. However, no response was observed in the third week, indicating weak oxidation. Notably, the high hydrophobicity of I-MXene contributed to its enhanced oxidation stability compared to as-prepared MXene in both ambient and aqueous environments, offering a promising solution for improving the long-term performance and reliability of MXene-based materials.

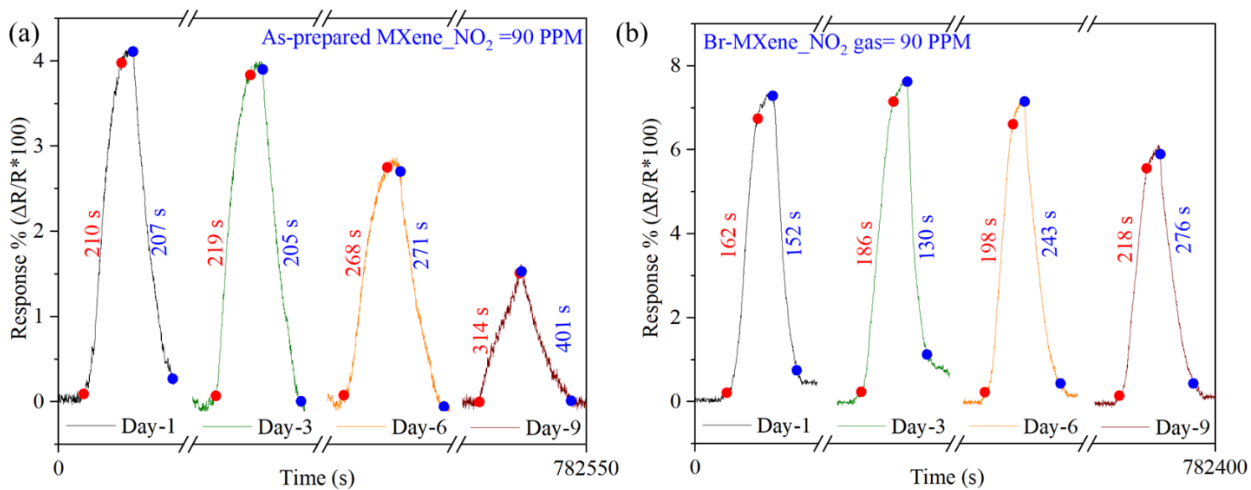

Fig. S20 Stability performances of (a) As-prepared- and (b) Br-MXene towards four pulses of NO₂ conducted over a 9-day period

S14 Gas sensing performances of Cl-MXene

SEM and XRD patterns (Fig. S6) confirm that Cl-MXene retained a higher Al content, as indicated by a slight downward shift in the (002) peak. Consequently, Cl-MXene exhibited higher resistance (15.5 K Ω) and limited response to 50 ppm of NO₂ (1.2%) when compared to our as-prepared multi-layered MXene. The improved performance of the as-prepared MXene is attributed to its larger interlayer separation achieved through greater Al etching.

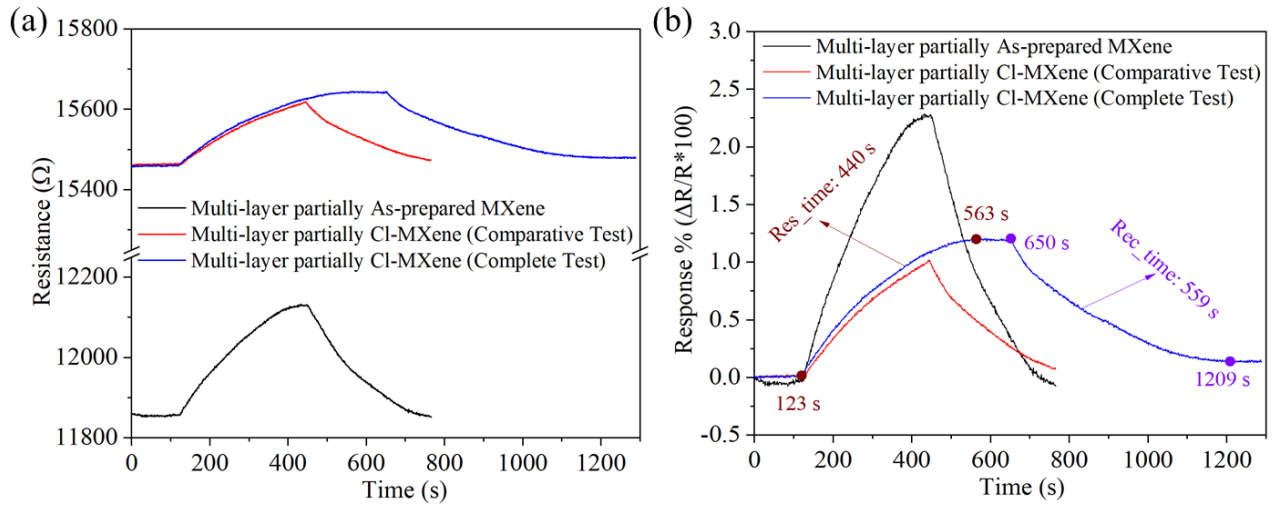

Fig. S21 Gas sensing response of Cl-MXene, multi-layered MXene and their comparison
