Bin Xie<sup>1,[2](http://orcid.org/0000-0002-4988-8894)</sup>, Yuanhui Guo<sup>1,2</sup>, Yun Chen<sup>1,2</sup>  $\bullet \otimes$ , Hao Zhang<sup>1,2</sup>, Jiawei Xiao<sup>1,2</sup>, Maoxiang Hou<sup>1,2</sup>, Huilong Liu<sup>1,2</sup>, Li Ma<sup>1,2</sup>, Xin Chen<sup>1,2</sup>, Chingping Wong<sup>3</sup>

- Comprehensively reviewed the progress in research on graphene electrode-based triboelectric nanogenerators (TENGs) from two dimensions, including precision processing methods of graphene electrodes and applications of TENGs.
- Discussed the various applications of graphene electrode-based TENGs in diferent scenarios, as well as the ways in which graphene electrodes enhance the performance of TENGs.
- Offered a prospective discussion on the future development of graphene electrode-based TENGs, with the aim of promoting continuous advancements in this feld.

**ABSTRACT** With the continuous development of wearable electronics, wireless sensor networks and other micro-electronic devices, there is an increasingly urgent need for miniature, flexible and efficient nanopower generation technology. Triboelectric nanogenerator (TENG) technology can convert small mechanical energy into electricity, which is expected to address this problem. As the core component of TENG, the choice of electrode materials signifcantly afects its performance. Traditional metal electrode materials often sufer from problems such as durability, which limits the further application of TENG. Graphene, as a novel electrode material, shows excellent prospects for application

in TENG owing to its unique structure and excellent electrical properties. This review systematically summarizes the recent research progress and application prospects of TENGs based on graphene electrodes. Various precision processing methods of graphene electrodes are introduced, and the applications of graphene electrode-based TENGs in various scenarios as well as the enhancement of graphene electrodes for TENG performance are discussed. In addition, the future development of graphene electrode-based TENGs is also prospectively discussed, aiming to promote the continuous advancement of graphene electrode-based TENGs.

# **1 Introduction**

The advent of artifcial intelligence (AI) and the Internet of Things (IoT) has led to the widespread application of wearable electronics. The issue of sustainable energy supply for these devices represents a pressing concern that must be addressed in the present era [[1–](#page-20-0)[4\]](#page-21-0). Conventional battery technologies necessitate frequent charging and replacement, thereby contributing to environmental pollution concerns [\[5](#page-21-1)]. The emerging triboelectric nanogenerator (TENG) has the potential to convert a wide range of mechanical energy sources  $[6, 7]$  $[6, 7]$  $[6, 7]$  $[6, 7]$ , including wind  $[8, 9]$  $[8, 9]$  $[8, 9]$  $[8, 9]$  $[8, 9]$ , wave  $[10-12]$  $[10-12]$  $[10-12]$ , raindrops [\[13](#page-21-8), [14](#page-21-9)], water mist [[15\]](#page-21-10), and human body movement  $[16, 17]$  $[16, 17]$  $[16, 17]$  into electricity through the coupled effect of contact charging and electrostatic induction [\[18](#page-21-13)[–20](#page-21-14)]. It is therefore anticipated that TENG technology will be able to address the aforementioned issues. Moreover, it provides a reliable energy source for wireless sensor networks, wearable electronic devices, and monitoring systems for health and environmental purposes.

As the key component of TENG, the choice of electrode material plays a critical role in the performance of TENG. Conventional metal electrodes have been identified as being vulnerable to corrosion, and graphene is considered a promising replacement material [[21–](#page-21-15)[24\]](#page-21-16). Due to its excellent electrical conductivity, high transparency, mechanical fexibility, and multifunctionality [[25\]](#page-21-17), graphene also shows great potential for applications in piezoelectric nanogenerators [\[26](#page-21-18)[–28](#page-21-19)], solar cells [[29\]](#page-22-0), microrobots [[30\]](#page-22-1), supercapacitors [\[31](#page-22-2), [32\]](#page-22-3), and sensors [[33–](#page-22-4)[35](#page-22-5)]. The studies of Wang et al. and Liu et al. in 2010 demonstrated the ability of graphene to store charge [[36,](#page-22-6) [37](#page-22-7)], increasing the applicability of graphene in TENG. In 2014 Kim et al. used graphene as an active material in energy-harvesting devices and systems, and fabricated the frst transparent fexible graphene-based TENG [[25](#page-21-17)]. Since then, a growing number of graphenebased electrodes for TENG have been developed [[14,](#page-21-9) [38](#page-22-8)[–42](#page-22-9)].

This review examines the research progress of graphene electrode-based TENGs is reviewed from two dimensions, including precision processing methods of graphene electrodes and applications of TENGs. A graphical abstract of this review is shown in Fig. [1](#page-2-0). First, multiple precision processing methods for graphene electrodes are described in detail. These methods are classifed into top-down and bottom-up processing methods based on the characteristics of the processing methods. Subsequently, the various applications of graphene electrode-based TENGs in energy harvesting, self-powered systems, and other felds are outlined. In addition, the efect of graphene and its derivatives as electrodes on the performance of TENG is discussed. Furthermore, the future directions and potential applications of graphene electrode-based TENG are explored, with the aim of providing valuable insights for the development and innovation in the relevant feld.

# **2 Precision Processing Methods for Graphene Electrodes**

The excellent electrical and mechanical properties of graphene have led to an increase in demand for this material as an electrode in TENGs. This has resulted in a growing need for precise and efficient processing methods for graphene electrodes. This section provides a summary of the reported precision processing methods for graphene electrodes used in TENGs. As with graphene synthesis methods [[54](#page-23-0)], these can be classifed as top-down or bottom-up, depending on the initiating material used.

#### **2.1 Top‑Down Methods**

The top-down graphene synthesis method employs graphite as the raw material to overcome van der Waals forces between graphene layers, thus enabling the fabrication of single or multiple layers of graphene [[55\]](#page-23-1). Consequently, the processing methods for several TENG electrodes described below are also dependent on graphene precursors and are thus classifed as top-down processing methods.

#### *2.1.1 Graphene Quantum Dots*

Graphene quantum dots (GQDs) are nanoscale carbon-based materials, typically fragments of graphene with dimensions at the nanoscale, featuring quantum size efects and large energy band gaps [[56,](#page-23-2) [57](#page-23-3)]. This subsection provides on an overview of the functionalization of GQDs by forming composites with other materials and discusses the properties of these GQDs, with a particular focus on their potential for application in electrodes for TENG.

<span id="page-2-0"></span>**Fig. 1** An overview of the latest research progress of graphene electrode-based TENG. GDQs. Reproduced with permission. As shown in Fig. [2a](#page-3-0), Xu et al. employed Ag nanowires (Ag NWs) coated with GQDs as the electrode for triboelectric electronic skin to increase the sensitivity to external mechanical stimulations [[58](#page-23-4)]. For the frst time, they modifed the Ag NWs with GQDs to improve the electron transfer process between the Ag NWs and polydimethylsiloxane (PDMS). The short-circuit current density is roughly 20 times greater than that of the device without GQDs. Hatta et al. developed a nanocomposite material, comprising PDMS as a polymeric matrix, barium titanite (BTO) nanopowders as dielectric fllers, and GQDs as conductive media (Fig. [2](#page-3-0)b) [[59](#page-23-5)]. With an increase in GQDs concentration, the nanocomposite flms become more crumpled, resulting in increased roughness. This crumpling efect also strengthens the electrostatic and π-π interactions between GQDs and PDMS. Moreover, a higher GQDs concentration facilitates uniform dispersion,

creating a network between the polymer matrix, BTO, and GQDs, ultimately enhancing the dielectric properties of the PDMS/BTO/GQDs samples. In a similar vein, Yang et al. fabricated an electrode for piezoelectric-triboelectric nanogenerator (PT-NG) modifcation by further adding GQDs to the PDMS (Fig. [2](#page-3-0)c) [\[60\]](#page-23-6). The resulting increase in triboelectric output is attributed to the improved dielectric properties of the PDMS flm doped with conductive GQDs and the enhanced efective contact caused by the change in PDMS surface microstructure. Moving on, as shown in Fig. [2](#page-3-0)d, Srivastava et al. frst reported the paddystraw-derived GQDs-reinforced vertical-aligned twodimensional (2D) ZnO nanosheet-based fexible TENG (FTNG) for scavenging mechanical energy [\[43](#page-22-10)]. Choi et al. fabricated polyvinylidene fuoride (PVDF)/GQDs composite nanofbers (NFs), which showed improved TENG per-formance (Fig. [2e](#page-3-0))  $[61]$  $[61]$  $[61]$ .

In summary, the excellent electrical properties of GQDs enable the efective improvement of dielectric performance in electrodes and the enhancement of output performance in TENG through doping.

#### *2.1.2 Graphene Nanosheets*

Graphene nanosheets (GNSs) are composed of a blend of monolayer graphene, multilayer graphene (2–10 layers), and nanostructured graphite. In other words, GNSs are a mixture of graphite and graphene, encompassing all types of 2D graphitic materials from those as thin as 0.34 nm to those as thick as  $100 \text{ nm}$  [[62](#page-23-9)]. GNSs serve as exceptional nanofllers because of their great mechanical, electrical, and thermal properties [[63](#page-23-10)]. It can be incorporated into composite materials to fabricate the precision electrode of TENGs with low interface resistance.

Irfan et al. developed a GNSs-flled PDMS matrix that could be used in a rolling-mode TENG (RL-TENG). GNSs were added to increase and optimize the electrical output by improving the dielectric constant of the PDMS friction layer (Fig. [3](#page-4-0)a) [[64\]](#page-23-11). Similarly, as shown in Fig. [3c](#page-4-0), Yang et al.

prepared a vertical contact-separated TENG composed of polyvinylidene fuoride (PVDF) and graphene oxide (GO) nanosheets. The electrospinning process used in preparing the composite nanofiber films provides a large effective area, augmenting the output of TENG [[65\]](#page-23-12). In another approach, Lin et al. proposed the construction of high-performance TENGs based on PVDF. They achieved this by incorporating GNSs into PVDF using electrospinning technology. The results demonstrated that both composition modulation with graphene and nanofiber structure fabricated through electrospinning contribute to the triboelectric performance enhancement of PVDF/G NF flms (Fig. [3b](#page-4-0)) [\[44](#page-22-11)].

In general, GNSs are typically employed as nanofllers to functionalize elastic polymers, such as PDMS and PVDF. This approach can efectively improve the dielectric constant of the friction layer and enhance the friction electrical properties, thereby improving the output performance of TENG.

#### *2.1.3 Water‑Exfoliated Graphene*

The exfoliation of graphene in water is a common method for the preparation of high-quality graphene flms [[66](#page-23-13)],

<span id="page-3-0"></span>**Fig. 2** Application of GQDs used as electrodes for TENG. **a** Schematic of the e-skin and the GQDs-coated Ag NW (G-Ag NW) network. Reproduced with permission. which can be utilized in energy harvesting through TENG. The integration of these flms with a variety of wearable and fexible technologies ofers new possibilities for the application of TENG in multiple felds.

As shown in Fig. [4](#page-5-0)a, Monica et al. proposed a novel method for assembling shear exfoliated graphene (SEG) in water. They demonstrated that SEG fakes suspended in a solution could be conveniently transferred onto various target substrates using the inter-digital transducer (IDT) technique for further applications. Additionally, the researchers combined a single SEG electrode with PDMS to create an active layer. This innovative combination resulted in the development of a fexible and semi-transparent TENG [[45](#page-22-12)]. And Ismael et al. presented TENGs using shear exfoliated graphene as electrodes as well as an active triboelectric layer deposited by a simple solution process. Graphene in combination with polymers such as PDMS was used to produce TENG devices using lowcost solution processing methods, which can be 40 times higher when compared to devices made with aluminum and PDMS [[67](#page-23-14)].

Based on water exfoliation, graphene can be readily deposited on various substrates, serving as electrodes for fexible TENG. This approach can be integrated with a range of wearable applications, thereby opening up new avenues

#### *2.1.4 GO & rGO*

Graphene oxide (GO) is a chemically modifed graphene, which is enriched with negative charges because it is decorated with oxygen functional groups both at the carbon network base planes and at the edges. Consequently, it is an appropriate material for use as a negative triboelectric material in the construction of electrodes for TENG [\[46](#page-22-13), [68](#page-23-15)].

for the utilization of TENG in a multitude of felds.

In 2016, Navjot et al. fabricated arch-shaped single electrode-based TENG using a thin flm of reduced graphene oxide nanoribbons (rGONRs). As shown in Fig. [5a](#page-6-0), the incorporation of rGONRs in PVDF polymer enhances the average surface roughness of rGONRs/PVDF thin flm, which improves the charge storage capacity of prepared film [[69\]](#page-23-16). The following year, Guo et al. reported a GO-based single-electrode TENG (S-TENG). By utilizing the ultrathin fexible GO flms, the as-fabricated S-TENGs present not only much higher energy harvesting efficiency but also great mechanical durability and low weight (Fig. [5](#page-6-0)b) [\[70\]](#page-23-17). And the same year, Wu et al. enhanced the output performance of the

<span id="page-4-0"></span>**Fig. 3** GNSs as fllers for electrodes. **a** Synthesis process of PDMS: GNSs composite material used in an RL-TENG. Reproduced with permission. TENGs (Fig. [5d](#page-6-0)) by introducing reduced graphene oxide (rGO) in the friction layer. The maximum output power density of a vertical contact-separation mode TENG with rGO sheets is 30 times larger than that of a device without rGO sheets [[71\]](#page-23-18). Additionally, in 2018, Viyada et al. introduced a novel method to enhance the properties of PDMS as a negative triboelectric material. They achieved this by incorporating GO and a sodium dodecyl sulfate (SDS) surfactant into the PDMS matrix. The modifcation of PDMS with GO and SDS resulted in improved performance in the TENG, which is shown in Fig. [5e](#page-6-0) [\[46\]](#page-22-13). In 2020, Zhou et al. fabricated a fexible and self-powered electronic skin (e-skin) based TENG (STENG). The rGO was used to construct a synergic conductive network with AgNWs to prepare stretchable electrodes for the STENG-based e-skin. the e-skin possesses a high sensitivity (78.4 kPa<sup>-1</sup>) as well as a fast response time (1.4 ms) toward pressure, exhibiting the potential prospect of a high-performance tactile sensor (Fig. [5](#page-6-0)c) [[50\]](#page-22-17).

In summary, GO and rGO are signifcant in the fabrication of precision electrodes for TENG devices. They can improve the power density and charge storage capacity of the electrodes, thereby enhancing the output performance of TENGs. These improvements hold great promise for applications such as enhancing energy harvesting efficiency,

improving mechanical durability and sensitivity, and achieving high-performance tactile sensors.

# **2.2 Bottom‑Up Methods**

Bottom-up graphene synthesis methods utilize a variety of carbon-containing precursors as feedstock, which are then subjected to a high-energy process of breakdown and conversion into graphene [[72\]](#page-23-19). In other words, these methods begin with smaller carbon-based precursor materials and incrementally build up layer-by-layer to produce graphene through a controlled process. The two approaches outlined below for fabricating graphene electrodes for TENG fall under the classifcation of bottom-up methods due to their adherence to these characteristics.

#### *2.2.1 Chemical Vapor Deposition*

Chemical vapor deposition (CVD) is a widely utilized technique for the manufacture of single-layer graphene on transition metal substrates [[73\]](#page-23-20). The graphene produced by this method is of a high quality, with the flm thickness and properties being able to be precisely controlled. This makes

<span id="page-6-0"></span>**Fig. 5** GO and rGO were used as electrodes for TENG. **a** Schematic view of the regions/PVDF-based TENG. Reproduced with permission. Reference [\[46\]](#page-22-13) Copyright 2018, American Chemical Society

it a crucial aspect of the manufacturing process of graphene electrodes for TENG.

In 2015, Bananakere et al. demonstrated a fexible and transparent TENG device based on graphene/EVA/PET electrodes. They proposed a roll-to-roll "green" method to transfer large-area graphene grown on copper foil by CVD onto fexible, transparent ethylene vinyl acetate/poly (ethylene terephthalate) (EVA/PET) plastic substrates (Fig. [6](#page-7-0)a) [[38\]](#page-22-8). In the same year, Smitha et al. presented a graphenebased TENG with a CVD grown graphene as the friction layer as shown in Fig. [6b](#page-7-0). This choice of graphene as the friction layer provides the TENG with electrical conductivity and high optical transmittance [\[74](#page-23-21)]. Additionally, in 2016, Hyenwoo et al. reported a conformal TENG with a graphene electrode. The graphene was grown on Cu foil by the thermal CVD method. The atomically thin thickness of graphene  $(< 1$  nm) enabled the TENG to have low flexural rigidity, facilitating conformal contact on human skin [[39\]](#page-22-20). As shown in Fig. [6c](#page-7-0), Yang et al. proposed a highperformance transparent and flexible TENGs based on CVD-grown graphene composite electrodes via surface engineering. And the output current density were enhanced by 140% to 2.4 μA cm<sup>-2</sup> [[75](#page-23-22)]. Lastly, in 2021, Han et al. proposed a noncontact TENG (nc-TENG). The high-quality graphene grown through CVD served as the electrode of the nc-TENG (Fig. [6d](#page-7-0)). By combining the optimization of hexagonal boron nitride (h-BN) and 1H,1H,2H,2H-perfuorooctyltrichlorosilane, they achieved an ultra-thin, stable, and high-output performance nc-TENG [[47](#page-22-14)].

The aforementioned studies underscore the potential of graphene in TENGs, which is produced through the CVD technique. The distinctive properties of graphene, including high electrical conductivity, mechanical flexibility, and transparency, render it an optimal material for enhancing the efficiency and functionality of TENGs. The incorporation of graphene into TENGs has led to the development of devices exhibiting enhanced performance, fexibility, transparency,

and conformal contact, opening up a range of potential applications.

#### *2.2.2 Laser‑Induced Graphene*

Laser-induced graphene (LIG) is a technology that directly converts polymers into graphene through laser irradiation. This method has attracted considerable interest due to its capacity to be fabricated directly onto a variety of carbon materials using a straightforward process [[76](#page-23-23), [77](#page-23-24)]. The favorable electrical conductivity, porous structure, and dopant modulation of LIG hold substantial promise in the realm of flexible wearable electronics and TENG applications [[78,](#page-24-0) [79](#page-24-1)].

In 2021, Chen et al. demonstrated an in situ growing LIG process that enables to pattern of superhydrophobic fuorinedoped graphene on fuorinated ethylene propylene (FEP) coated polyimide (PI). This method leverages distinct spectral responses of FEP and PI during laser excitation to generate the environment preferentially for LIG formation, eliminating

<span id="page-7-0"></span>**Fig. 6** CVD-grown graphene is used for the electrode of the TENG. **a** Schematic illustration of the roll-to-roll delamination of copper and graphene onto EVA/PET substrate. Reference [\[74\]](#page-23-21) Copyright 2016, Elsevier. **c** Schematic diagram of GF-based TENG. Reproduced with permission. Reference [\[75\]](#page-23-22) Copyright 2017, American Chemical Society. **d** Structure of an nc-TENG. Reproduced with permission. Reference [\[47\]](#page-22-14) Copyright 2021, American Chemical Society

the need for multistep processes and specifc atmospheres. The structured and water-repellant structures rendered by the spectral-tuned interfacial LIG process are suitable as electrodes for the construction of a fexible droplet-based electricity generator (DEG) (Fig. [7](#page-9-0)a) [\[14](#page-21-9)]. In 2019, Michael et al. showcased various architectural designs for TENGs utilizing LIG composites (Fig. [7b](#page-9-0)), which exhibited a high-power output of  $0.76$  W m<sup>-2</sup>, pioneering the field of LIG-based TENGs [\[80\]](#page-24-2). And the same year, Jiang et al. fabricated a highly fexible and efective TENG based on MXene and PDMS composite PDMS/MXene flm and LIG electrode. As shown in Fig. [7](#page-9-0)c, the developed TENG not only realizes efective harvesting of leaf swing energy and human writing energy but also can be utilized to recognize a real-time trajectory. This fexible TENG has enormous potential in the felds of energy harvesting and sensing [\[81\]](#page-24-3). Next year, Xia et. al presented a LIG-based pressure sensor (Fig. [7d](#page-9-0)). The LIG not only contributes to the sensitivity of pressure sensors but also improves the transfer charge density of TENG [[82\]](#page-24-4). As shown in Fig. [7e](#page-9-0), Kumar et al. proposed a Siloxene/Ecofex nanocomposite-based highperformance contactless TENG also in 2022. The introduction of LIG as a charge-trapping intercalation layer increases the surface potential by four-fold, resulting in improved output performance of the TENG [\[49\]](#page-22-16). In 2023, Guo et al. developed one device integrated by two diferent working-mode laserinduced graphene (LIG)-based TENG (Fig. [7](#page-9-0)f). Thanks to the high-precision machining of LIG, the device can achieve simultaneously its accurate wireless control and tactile pattern recognition capability [[83\]](#page-24-5). And the same year, Kumar et al. designed a breathable triboelectric sensor (Fig. [7g](#page-9-0)). The LIG as a charge-collecting electrode was successfully transferred to the porous substrate, which was conformally attached to the substrate. This reduces interfacial resistance and minimizes the redundancy of using complex manufacturing techniques [[84](#page-24-6)].

In summary, LIG has demonstrated its versatility with a multitude of applications and notable advantages. Devices based on LIG exhibit fexibility, high-precision control, and the ability to perform a variety of functions. The method offers diverse material options, environmental friendliness, and customizable patterns. Among the precision processing methods previously mentioned, LIG technology is considered the most scalable. Furthermore, LIG flms can function as energy harvesting systems, sensors, and contactless devices. When used as an electrode in TENG, LIG can enhance sensitivity, transfer charge density, and output performance,

rendering it a promising material for a wide range of technological advancements.

# **3 Applications of Graphene Electrode‑Based TENG**

This section will present the applications of graphene electrode-based TENG in various felds. In order to gain a comprehensive understanding of the diverse applications of graphene electrode-based TENG, it is necessary to examine several key aspects, including energy harvesting, self-powered sensor systems, the enhancement of TENG performance, and other potential applications.

#### **3.1 Energy Collection**

In terms of energy collection, while the ability to collect energy is a common feature of all TENGs, the excellent electrical conductivity and mechanical strength of graphene electrodes, as well as the ability to be doped, offer greater potential for energy collection in TENGs. Consequently, the distinctive properties and advantages of graphene are exploited in a variety of contexts to enhance the efficiency and dependability of energy harvesting capabilities through meticulous design and optimization, thereby maximizing the potential for energy collection in TENGs.

In 2021, Chen et al. developed a raindrop energy collecting TENG based on F-LIG, shown in Fig. [8a](#page-10-0). The TENG exhibited a peak power density of 47.5 W m<sup>-2</sup> when a water droplet (105 µL) was released from a height of 25 cm. This device could light up 480 LEDs, showcasing a greatly expanded energy harvesting range [[14\]](#page-21-9). In 2018, Zhang et al. reported a rGobased self-cleaning/charging power system (SPS), which can be exploited to convert and store energy from falling raindrops directly to provide a stable and durable output. The device can light a light-emitting diode for more than 300 s (Fig. [8](#page-10-0)b) [[48\]](#page-22-15). Additionally, in the same year, Sai et al. reported a novel additively manufactured gPLA nanocomposite-based high-performance TENG (Fig. [8c](#page-10-0)). The W-TENG generates very high output voltages  $> 2$  kV with a strong electric field that enables the wireless transmission of harvested energy over 3 m [\[85\]](#page-24-7). In 2019, Jiang et al. developed a highly fexible MXene-enabled porous flm, which was then integrated with LIG electrode to fabricate TENG. This high-performance MXene-enabled

<span id="page-9-0"></span>**Fig. 7** LIG is used as an electrode in TENG. **a** Schematic diagram of interfacial laser-induced F-LIG. Reproduced with permission. TENG presents versatile applications in harvesting energy from leaf swing and human writing (Fig. [8](#page-10-0)d) [[81\]](#page-24-3). Furthermore, in 2020, Li et al. developed an integrated self-cleaning and self-charging device based on LIG. The device is capable of harvesting energy from the swinging crop leaves and raindrops. The lotus leaf-like structure enhances the self-cleaning ability of the device and self-cleaning ability allows this device to work reliably in a humid environment (Fig. [8](#page-10-0)e) [\[86](#page-24-8)].

The graphene electrode-based TENG has demonstrated to possess a number of advantages in the feld of energy harvesting. It is capable of converting and storing energy from a variety of sources including raindrops, oscillating objects, and human movement. The device can achieve high power density, generate high output performance, and have the capability of wirelessly transmitting the collected energy. Additionally, the devices can self-clean and operate reliably in various environments. These characteristics render the graphene electrode-based TENG a versatile and efficient energy-harvesting solution.

#### **3.2 Self‑Powered Sensor Systems**

The exponential growth of AI and IoT has led to a surge in demand for sensors, with the issue of their power supply becoming increasingly pressing. One potential solution to this problem is the development of self-powered sensors that obtain energy from the surrounding environment to power themselves [[87\]](#page-24-9). TENG can be efectively used as a novel self-powered sensing technology, which is extensively employed in human body monitoring, alarm systems, electronic skin and other applications in daily life.

#### *3.2.1 Physical Sensing Technologies*

This section will focus on exploring the practical applications of TENG in sensing physical quantities such as pressure, vibration, strain, and humidity [[88](#page-24-10)[–91](#page-24-11)]. Building upon the exploration of practical applications of TENG in sensing physical quantities, it is evident that innovative advancements have been made in various felds.

<span id="page-10-0"></span>**Fig. 8** Graphene electrode-based TENG is used for energy collection. **a** Working mechanism of F-LIG-based DEG. Reproduced with permission. Reproduced with permission. Reference [\[86\]](#page-24-8) Copyright 2020, Elsevier

For instance, in 2021, Yan et al. constructed a smart wireless-controlled HMI system that can wirelessly control personal electronics. The system is composed of a 9-digit arrayed touch panel based on a LIG-patterned TENG (Fig. [9a](#page-12-0)) [\[92](#page-24-12)]. Furthermore, in 2022, Luo et al. proposed a LIG-based selfpowered vibration sensor that shows its potential to operate on curved machines and track the intensity of human activities. As shown in Fig. [9b](#page-12-0), the sensor can efectively distinguish slip from walking, jumping and running [[93\]](#page-24-13). Further advancements in 2022 Xia et al. constructed a smart self-powered measurement-control combined system consisting of the LIGbased pressure sensors and TENG (Fig. [9c](#page-12-0)) [[82](#page-24-4)]. Additionally, in the same year, Hu et al. developed a hydrogel-based sensor that exhibited ultra-sensitive pressure strain sensing performances. It could be utilized to recognize diferent utterances when attached to the surface of the throat [\[94](#page-24-14)]. The hydrogelbased sensor was also used as a bioelectrode to detect human electrophysiological (EP) signals. Additionally, Kumar et al. demonstrated the  $MoS<sub>2</sub>/LIG$  based TENG (Fig. [9](#page-12-0)d) displays outstanding humidity sensing qualities, boasting a sensitivity of 0.45 V/%. This device shows great potential for touchless interactions and minimizing potential contact scenarios [[49\]](#page-22-16). Dai et al. presented a fexible and multifunctional hydrogel (GPPD-hydrogel) for use in wearable strain sensors and fexible TENG (Fig. [9e](#page-12-0)). The sensor is capable of withstanding temperatures as low as −80 °C and demonstrates an ultra-high stretchability of up to 2,000% [\[95](#page-24-15)]. Lastly, in 2023, Guo et al. designed a LIG-based tactile sensing array that can achieve tactile imaging and pattern recognition. The device, shown in Fig. [9](#page-12-0)f, can be employed for accurate wireless control and realtime tactile sensing, with a pressure sensitivity of  $2.2 \text{ V kPa}^{-1}$ within the range of 0–2.8 kPa [[83](#page-24-5)].

In summary, these sensors share the common feature of utilizing graphene-based advanced materials for enhanced sensing capabilities. These sensors have demonstrated applications in various felds. The integration of TENG with

other materials and technologies has led to the development of smart and efficient systems for wireless control, real-time sensing, and interaction with personal electronics. Overall, the diverse applications and capabilities demonstrated in the feld of TENG indicate promising directions for future research and technological advancements.

#### *3.2.2 Graphene‑Based E‑Skin*

Advanced technologies are increasingly needed to enable natural and efficient communication between humans and machines. Graphene-based electronic skin (e-skin) technology has emerged as a promising solution [\[96\]](#page-24-16). The unique properties of graphene, including its flexibility, conductivity, and transparency, have paved the way for the development of highly sensitive and responsive e-skin systems that mimic the capabilities of human skin.

Shin et al. fabricated a fexible and semi-transparent SE-TENG in 2018. The SE-TENG capability to generate electricity was demonstrated by connecting it to fve LEDs under releasing and approaching mode (Fig. [10](#page-13-0)a) [\[45\]](#page-22-12) and proving the potential for its application in e-skin. In the same year, Xu et al. demonstrated a cuttable, transparent, stretchable, and lightweight e-skin (Fig. [10b](#page-13-0)) [\[58](#page-23-4)]. By incorporating well-designed micro-gaps, this e-skin demonstrated enhanced sensitivity to various mechanical stimuli such as pressing, stretching, folding, and twisting. In 2020, Zhou et al. fabricated a fexible and self-powered electronic skin (e-skin) using an ultra-stretchable TENG. The e-skin exhibits high sensitivity (78.4 kPa<sup>-1</sup>) and a fast response time (1.4 ms) to pressure, showcasing its excellent tactile sensing capabilities (Fig. [10](#page-13-0)c) [[50\]](#page-22-17). In 2022, Sun et al. proposed a dual-function acoustic Human–Robot Interaction (HRI) device based on graphene, known as GHRI. This device combines sound sensing (acting as an artifcial ear) and emission (acting as an artifcial mouth) functionalities in a single unit. By incorporating machine learning algorithms, the GHRI enables advanced speech recognition and communication capabilities, as illustrated in Fig. [10](#page-13-0)e [[97](#page-24-17)]. In 2023, Kumar et al. developed a breathable triboelectric sensor based on graphene (Fig. [10](#page-13-0)d) [[84](#page-24-6)]. This sensor was successfully employed in gesture recognition applications, highlighting its versatility in human–machine interfaces and soft robotics systems.

In summary, graphene-based e-skin technologies are paving the way for more intuitive and seamless human–machine interactions. With advancements such as the dual-function GHRI device, fexible and self-powered e-skin, semi-transparent SE-TENG, cuttable and stretchable e-skin, and breathable triboelectric sensor, the possibilities for enhancing communication and sensory capabilities between humans and machines are endless. These innovations not only demonstrate the potential of graphene in revolutionizing human–machine interactions but also hold promise for the future of technology and robotics.

#### *3.2.3 Human Body Monitoring*

As wearable technology continues to progress, the integration of self-powered sensors for human body monitoring is increasingly vital. The advancements in self-powered sensor technology have transformed the feld of human body monitoring, allowing for real-time data collection and analysis in diverse applications [[98–](#page-24-18)[100\]](#page-24-19).

In 2019, Maitra et al. demonstrated a triboelectrically driven self-charging and self-healing ASC (SCSHASC) power cell (Fig. [11a](#page-15-0)). This power cell can be charged through casual body or limb movements (bio-mechanical motions) [\[101](#page-24-20)]. Additionally, these innovative self-powered wearable sensors, such as the liquid electrode-based TENG with graphene oxide micro/nanosheets electrode developed by Zhao et al. [\[102](#page-24-21)]. The device is anti-freezing and stretch-matched, making it suitable for use as a self-powered wearable sensor attached to the human body for monitoring biomechanical motion (Fig. [11b](#page-15-0)). In 2022, Yang et al. introduced a method where they combined a polydimethylsiloxane (PDMS) layer containing graphene oxide (GO) to create a fabric-based TENG. This TENG allows for the conversion of various forms of mechanical energy obtained from body motion into electronic signals, which can then be displayed on a computer (Fig. [11c](#page-15-0)) [[51\]](#page-22-18). In 2023, Liu et al. proposed a fully degradable TENG with graphene composite paper as electrodes. It could charge up diferent electronic devices, monitoring human motions (Fig. [11d](#page-15-0)). The TENGs offer the capability to monitor biomechanical motion and human movements with high accuracy and efficiency  $[103]$  $[103]$ . In the same year, Xiong et al. developed a consecutive and scalable process for graphene textile TENGs (Fig. [11e](#page-15-0)) [[104](#page-25-1)]. These TENGs have demonstrated high flexibility, shape

<span id="page-12-0"></span>**Fig. 9** Graphene electrode-based TENG is used for physical sensors. **a** Fabrication and schematic of fexible high-resolution triboelectric sensing array based on LIG. adaptability, and structural integrity, making them suitable for energy harvesting and human motion recognition. Yang et al. reported on an intrinsically stretchable TENG that integrates Ag NWs/LIG electrodes with triboelectric MXene/ PDMS-Ecofex composites (Fig. [11](#page-15-0)f) [\[105](#page-25-2)]. This innovation aims to achieve efficient mechanical energy harvesting and self-powered biomechanical sensing.

In summary, the evolution of self-powered sensors for monitoring the human body is revolutionizing the wearable technology feld. These devices, such as the self-power

<span id="page-13-0"></span>**Fig. 10** Graphene electrode-based TENG is used for e-skin. **a** Flexible and semi-transparent SE-TENG device comprising a PDMS and SEGcoated PET flm by IDT. TENGs with graphene electrodes, enable real-time data collection and analysis in various applications, including biomechanical sensing. With advancements in this technology, monitoring biomechanical motion and human movements with great accuracy and efficiency has become achievable, paving the way for enhanced healthcare, sports performance, and overall well-being.

#### *3.2.4 Alarm System*

Graphene electrode-based TENG has emerged as a key technology in the development of advanced alarm systems. These TENG devices offer high sensitivity and self-powering capabilities, enabling the design of innovative alarm systems that can efectively monitor and detect potential dangers.

In 2020, Liu et al. demonstrated a self-powered forest fre alarm system (Fig. [12a](#page-16-0)). The self-powered FFAS based on TENG achieves a low-temperature response (160 $\degree$ C), the rapid response time  $(\sim 3 \text{ s})$ , and especially no external power source supply for early forest fre monitoring and detection [[52\]](#page-22-19). Furthermore, in the same year, He et al. designed a safety warning device that can monitor carpet signals using a GO-based TENG. When a person walks by, their sole contacts and separates from the fabric, generating a signal that is then transmitted to the programming system (Fig. [12b](#page-16-0)) [\[106\]](#page-25-3). In 2022, Yu et al. designed a breathing alarm device for humans (Fig. [12c](#page-16-0)) [[107](#page-25-4)]. The device utilized an rGO- $TiO<sub>2</sub>$  humidity sensor as the respiratory sensing component, which features high responsiveness, fast response and recovery times, high reversibility, minimal hysteresis, and excellent stability. Additionally, in 2022, Wang et al. developed a graphene-based TENG with anti-impact and sensing performance for wireless alarm systems. The system, shown in Fig. [12d](#page-16-0), designed with high sensitivity, is intended to monitor and alert users to potential impact dangers, thereby paving the way for the advancement of nextgeneration intelligent protective clothing [[108\]](#page-25-5). Moreover, in 2023, Liu et al. developed a burglar alarm that can be placed under the doormat when the homeowner leaves the house. Should any strangers attempt to enter the house and step on the doormat, the FD-TENG sensor will be triggered and generate a voltage signal, activating the buzzer and LED lamp in the alarm system (Fig. [12e](#page-16-0)) [\[103\]](#page-25-0). Recently, Luo et al. proposed a living plant leaf-based TENG(LPL-TENG) for self-powered smart agriculture sensing (Fig. [12f](#page-16-0)), the feature

of alarming at high wind speed can also be exhibited by the LPL-TENG to realize remote control [[109](#page-25-6)]. In the same year, Wang et al. designed a hydrogen leakage alarm to ensure the safety and stability of the hydrogen production process. At a wind speed of  $4.5 \text{ m s}^{-1}$ , the wind-driven TENG consistently powered real-time monitoring, wireless transmission, and hydrogen leakage alarm (Fig. [12](#page-16-0)g) [\[53](#page-23-8)].

In summary, graphene electrode-based TENG have transformed the landscape of alarm systems with their high sensitivity and self-powering capabilities. These innovative devices have been successfully incorporated into a variety of applications, including forest fre detection, impact sensing in protective suits, human respiration monitoring, and smart agriculture, enhancing safety measures in all aspects of life and enabling real-time monitoring of potential hazards. As research and development in TENG technology continue to advance, the future of alarm systems looks promising, offering increased safety and security in a wide range of scenarios.

#### **3.3 Performance Improvement of TENG**

As research on TENG continues to intensify, it becomes crucial to explore strategies to enhance the performance of TENGs. The studies mentioned in the following text shed light on the successful integration of graphene and its derivatives in TENG devices, demonstrating their potential to significantly improve power output and efficiency. By understanding these advancements, we can grasp the importance of these integrations and their implications for the further development and application of TENG technology.

As shown in Table [1,](#page-17-0) Zhang et al. embedded graphene sheets in carbon for TENG electrodes, resulting in higher electric output performance compared to the original TENG. The peak power density increased from 0.5 to 0.63 mW  $cm^{-2}$ , raising efficiency by  $20\%$  [\[110](#page-25-7)]. According to Fatemeh et al., the incorporation of GO within micro-patterned PDMS at 1 wt% (PDMS@1CGO) significantly enhanced the triboelectric characteristics. The output performance of the micropatterned film was improved by 46% [[111\]](#page-25-8). Chen et al. developed a stretchable TENG based on stretchable crumpled graphene that enhances performance. The power density is 0.25 mW cm−2, which is 20 times higher than that of a planar graphene-based TENG [\[112](#page-25-9)]. Chen et al. demonstrated a

<span id="page-15-0"></span>**Fig. 11** Graphene electrode-based TENG is used for human body monitoring. **a** TENG-driven self-charging and self-healing fexible asymmetric supercapacitor power cell. Reference [\[53\]](#page-23-8) Copyright 2023, Elsevier

in improved output performance. The optimal power density reached  $675 \text{ mW m}^{-2}$ , which was approximately 5.05 times higher than that of the TENG employing copper electrodes [[103](#page-25-0)]. Shi et al. fabricated high-performance TENGs by incorporating graphene nanosheets using electrospinning technology. The resulting TENGs exhibited a maximum peak power density of 130.2 W m−2, which was nearly eight times higher compared to the original TENG [[44\]](#page-22-11). Huang et al. modifed the surface electrifcation of the triboelectric

materials and enhanced the output performance of the TENG by embedding GO in the PVDF matrix. As a result, the power density experienced a remarkable increase of 513% [[114\]](#page-25-11). Viyada et al. achieved an enhanced power output of a TENG by utilizing GO and sodium dodecyl sulfate to modify PDMS. The resulting power output values were threefold higher than those of the fat PDMS confguration [[46\]](#page-22-13). Kinas et al. significantly enhanced the output voltage of the TENG by grafting reduced graphene oxide (rGO) and

Graphene electrode types	Enhanced power density (mW $cm^{-2}$ )	Increased efficiency (%)	Refs

GQDs	0.0027	277	[61]

<span id="page-17-0"></span>**Table 1** Enhancement of TENG performance by various types of graphene electrodes

carbon nanotubes (CNT) onto polyacrylonitrile (PAN). This modifcation resulted in a remarkable increase of 125% in the maximum peak power density [[115\]](#page-25-12). Hatta et al. prepared a mixture of PDMS/BTO doped with GQDs and mechanically stirred it. The resulting TENGs exhibited an output performance that was 2 times higher compared to nanocomposite flms without GQDs [\[59](#page-23-5)]. Choi et al. found that the optimal amount of GQD incorporation stimulated the formation of the polar β-phase and enhanced the performance of TENG. The maximum output power from TENG devices increased from 35 to 97  $\mu$ W [\[61](#page-23-7)].

In summary, the incorporation of graphene and its derivatives in TENG devices has consistently demonstrated signifcant improvements in power output and performance compared to the original TENG. These improvements are important for the efficiency and performance enhancement of TENG and provide strong support for the further development and application of TENG technology.

#### **3.4 Other Applications**

These innovative applications of graphene electrode-based TENG demonstrate the diverse range of possibilities in various fields. Researchers are continuously exploring new ways to utilize graphene in unique and breakthrough applications, demonstrating the potential for further advancements in renewable energy and environmental protection.

In 2021, Shen et al. developed a distinctive hybrid system by combining a self-powered TENG with a three-dimensional graphene oxide photocatalyst doped with carbon dots-TiO<sub>2</sub> sheets (Fig.  $13a$  $13a$ ). The power generated by the TENG can be used directly for wastewater purifcation, showcasing a self-powered electrocatalytic technology [[116](#page-25-13)]. In 2023, Marziyeh et al. created a composite TENG consisting of polypyrrole-graphene oxide (PPy-GO) with enhanced electrical outputs and bactericidal properties (Fig. [13b](#page-18-0)). The fndings illustrate that the combination of GO nanosheets and TENG-generated electrical stimuli had a synergistic efect, leading to enhanced ROS generation and the rupture of the cellular membrane in *S. aureus* as the bacterial model [\[117](#page-25-14)]. In 2023, Rumana et al. developed an affordable and innovative nanocomposite-based TENG (NC-TENG) utilizing reduced graphene oxide (rGO). The NC-TENG (Fig. [13c](#page-18-0)) is showcased as a humidity sensor, Morse code generator, and smart water dispenser [\[118](#page-25-15)]. 2024 Wang et al. demonstrated P-doped  $W<sub>2</sub>C$  nanoparticles anchored on graphene ( $P@W_2C-C$ ) as a highly effective electrocatalyst for the hydrogen evolution reaction, powered by a wind-driven TENG (Fig. [13d](#page-18-0)). They successfully achieved a hydrogen production rate of 64.5  $\mu$ L min<sup>-1</sup> and implemented a selfawakening hydrogen leakage alarm system [[53\]](#page-23-8).

As described earlier, there exists some graphene electrode-based TENGs that can drive miniature commercial electronic devices [\[109,](#page-25-6) [118](#page-25-15)]. However, achieving widescale commercialization involves several challenges as follows. Firstly, consistency and stability: while graphene electrode-based TENGs perform well in small-scale experiments, it is crucial to ensure the technology's consistency and stability under various environmental conditions in commercial applications. Secondly, standardization: the standardization of technology can impact its adaptability and scalability across diferent application scenarios. Developing and adhering to relevant industry standards can facilitate better market integration. Finally, demand and acceptance: the commercialization of the technology requires careful consideration of market demand and acceptance, necessitating thorough market research. Therefore, the primary challenge

<span id="page-18-0"></span>Fig. 13 Graphene electrode-based TENG is used for other applications. a Schematic illustration of high-efficiency wastewater purification system based on TENG. Reproduced with permission. Reference [[53](#page-23-8)] Copyright 2022, Elsevier

for graphene electrode-based TENGs in commercial applications lies in validating performance beyond lab-scale environments and addressing issues such as cost, reliability, and integration.

In summary, the continuous exploration and development of graphene electrode-based TENG highlight the immense potential for further innovation in the felds of renewable energy and environmental protection. These advancements

<span id="page-19-0"></span>**Fig. 14** Prospects for the development of graphene electrode-based TENG

underscore the importance of harnessing the unique properties of graphene to drive sustainable solutions and pave the way for a greener, more efficient future and commercial applications.

# **4 Conclusions and Prospects**

This review outlines the signifcant developments in graphene electrode-based TENG research that have been made in recent years. As a naturally self-powered device, TENG can efectively address the issue of energy supply for microdevices such as wearable electronics. Graphene and its derivatives were processed as electrodes for TENG by both top-down and bottom-up methods, which resulted in a notable enhancement in power output and performance. The exceptional electrical conductivity, mechanical strength, and dopability of graphene facilitate the enhancement of TENG efficiency and reliability in energy harvesting. Its excellent fexibility, conductivity, and transparency can be employed to develop highly sensitive and responsive e-skins, as well as to enable highly accurate and efficient monitoring of human motion and sensing. Furthermore, graphene electrode-based TENG technology has the potential to contribute to the development of renewable energy and environmental protection, including the production of hydrogen and the purifcation of water.

With the continuous expansion of graphene's use in TENGs, future research will focus on developing graphene with enhanced properties. Consequently, technologies for processing high-performance graphene are constantly evolving, including doping, surface functionalization, and other methods. For example, doping with nitrogen, boron, or transition metals can signifcantly enhance its electrical conductivity and catalytic activity, thus improving the energy harvesting efficiency of TENGs. Additionally, functionalization technologies, which involve adding chemical groups to graphene's surface, can customize its properties for specifc applications and enhance the stability of the electrode, ultimately increasing the robustness of the TENG system. Therefore, advancements in graphene processing technology are driving TENGs toward becoming self-powered wearable sensing systems with high energy harvesting efficiency, long life, and high stability. In addition, exploring alternative materials to graphene for TENG electrodes, such as 2D materials like MXenes, is also a promising research direction.

To advance the development of graphene-based TENGs, several challenges must be addressed. For example, using naturally degradable materials (e.g., cork and fruit shells) as carbon precursors in LIG and enabling precise pattern customization can improve material utilization efficiency and reduce waste generation, thereby achieving environmentally friendly processing. To ensure processing consistency, errors can be minimized by improving the stability of the laser light source and increasing the precision of the processing platform. Additionally, pre-treating raw materials to reduce defects is benefcial. Furthermore, gaining a deeper understanding of the charge transfer mechanisms between graphene-based TENG electrodes and modifying surface morphology to increase electrode contact area are essential for improving energy harvesting efficiency. The robustness of the system can be improved by targeted functionalization of the electrode surface to increase the long-term life cycle and high stability of the system.

As the feld of graphene electrode electrode-based TENG technology continues to evolve, self-powered graphene electrode-based TENGs are poised to become a valuable addition to the technology landscape. This review proposes the following outlooks for future research and practical applications (Fig. [14](#page-19-0)).

- (1) **Processing techniques**: The majority of the previously mentioned top-down methods incorporate graphene and its derivatives into polymers such as PDMS and PVDF to form composite materials, which are used as electrodes for TENGs. Although these methods can enhance the performance of TENG, the synthesis process of electrode materials is arduous, and some of the methods present safety hazards and generate waste materials. Among the bottom-up methods, the CVD method has high equipment maintenance costs. Furthermore, the LIG processing method is prone to defects in the graphene. Developing greener synthesis methods is crucial for improving environmental sustainability in graphene production. Consequently, future research may be directed toward the development of an environmentally friendly and cost-effective electrode fabrication method based on natural materials. Future strategies might focus on optimizing production techniques and enhancing material utilization efficiency to ensure the environmental sustainability of graphene production.
- (2) **System integration**: TENG is a device that converts the energy of the surrounding environment into electricity. The peak power density of graphene electrodebased TENG is close to hundreds of watts per square meter, which is fully capable of storing and powering electronic devices. Kumar et al. integrated TENG and supercapacitor into a single device, thereby achieving system integration of energy harvesting and storage. This was applied to a self-powered smart switching system [\[119](#page-25-16)]. In light of the potential applications of graphene electrode-based TENGs in self-powered systems, future research may be directed toward the development of TENGs with high-performance energy storage systems.
- (3) **Intelligent terminals**: The issues of human health and environmental protection remain at the forefront of public concern. The potential of graphene electrodebased TENG has already been demonstrated in a number of applications, including human movement monitoring, wastewater purification, hydrogen production and sterilization. The integration of

TENG-based self-powered systems with the Internet of Things (IoT) will result in the development of smart terminal systems for the real-time monitoring of human health and environmental energy. This will facilitate the early detection of potential issues and enable the implementation of corrective measures.
